

Diagrammatic Algebra of First Order Logic

**joint work with Filippo Bonchi and Alessandro Di Giorgio, U. Pisa and
Nathan Haydon, Tallinn University of Technology**

**Pawel Sobocinski, Tallinn University of Technology
Resources and Co-resources Workshop, Cambridge, 19 July 2023**

Two starting points

- **Aurelio Carboni and RFC Walters (1987) Cartesian Bicategories**
 - **an algebra of relations with the expressive power of regular logic**
- Charles Peirce's Calculus of Relations (1883)
 - featuring linear distributivity and linear adjoints

Towards cartesian bicategories i

- Lawvere in the 1960s realised the power of **cartesian categories**
 - **free cartesian categories** on a signature are the same as categories of terms and substitutions (**classical syntax**)
 - cartesian category induced by a (presentation of an) algebraic theory is a **presentation-independent** notion of algebraic theory in the universal algebraic sense
 - **functorial semantics**: models are cartesian functors to \mathbf{Set} , homomorphisms are natural transformations

Aside - Fox's theorem

- A category is cartesian iff it is symmetric monoidal st every object is equipped with a cocommutative **comonoid structure**

- which is **natural**

- and **coherent**

Towards cartesian bicategories ii

- But what if one wants to move to more expressive theories?
 - e.g. what if one wants models in **Rel**?
 - **Rel** = category with objects sets and arrows $X \rightarrow Y$ relations $R \subseteq X \times Y$
 - composition $x (R ; S) z$ iff $\exists y. xRy \wedge ySz$
 - identities are $x I y$ iff $x=y$
- Cartesian product is **still** important (n-ary relations can be seen as a relation of type $X^n \rightarrow 1$)
- But cartesian product is **not** the categorical product in **Rel**...
- Note though: it does make **Rel** a symmetric monoidal category and every homset is a poset

Cartesian bicategories

- every homset is a poset
- every object X is equipped with a cocommutative comonoid structure

$$\begin{array}{c} X \\ \hline \bullet \\ \hline X \\ \hline X \\ \hline X \end{array} \stackrel{(\leftarrow^\circ\text{-as})}{=} \begin{array}{c} X \\ \hline \bullet \\ \hline X \\ \hline X \\ \hline X \end{array} \quad \begin{array}{c} X \\ \hline \bullet \\ \hline X \end{array} \stackrel{(\leftarrow^\circ\text{-un})}{=} \begin{array}{c} X \\ \hline \hline X \end{array} \quad \begin{array}{c} X \\ \hline \bullet \\ \hline X \\ \hline X \\ \hline X \end{array} \stackrel{(\leftarrow^\circ\text{-co})}{=} \begin{array}{c} X \\ \hline \bullet \\ \hline X \\ \hline X \\ \hline X \end{array}$$

- but now the naturality is only weak

$$\begin{array}{c} X \\ \hline \boxed{c} \\ \hline \bullet \\ \hline Y \\ \hline Y \end{array} \stackrel{(\leftarrow^\circ\text{-nat})}{\leq} \begin{array}{c} X \\ \hline \bullet \\ \hline \boxed{c} \\ \hline Y \\ \hline Y \end{array} \quad \begin{array}{c} X \\ \hline \boxed{c} \\ \hline \bullet \end{array} \stackrel{(!^\circ\text{-nat})}{\leq} \begin{array}{c} X \\ \hline \bullet \end{array}$$

- and there is new structure!
 - the comonoid structure has **right adjoints**

$$\begin{array}{c} X \\ \hline \bullet \\ \hline X \end{array} \stackrel{(\epsilon!^\circ)}{\leq} \begin{array}{c} X \\ \hline \hline X \end{array} \quad \begin{array}{c} X \\ \hline \bullet \\ \hline X \\ \hline X \\ \hline X \end{array} \stackrel{(\epsilon^\leftarrow^\circ)}{\leq} \begin{array}{c} X \\ \hline \hline X \\ \hline X \\ \hline X \end{array} \\
 \begin{array}{c} X \\ \hline \hline X \end{array} \stackrel{(\eta!^\circ)}{\leq} \begin{array}{c} X \\ \hline \bullet \\ \hline \bullet \\ \hline X \end{array} \quad \begin{array}{c} X \\ \hline \hline X \end{array} \stackrel{(\eta^\leftarrow^\circ)}{\leq} \begin{array}{c} X \\ \hline \bullet \\ \hline \bullet \\ \hline X \end{array}$$

- and together they satisfy the **Frobenius equation**

$$\begin{array}{c} X \\ \hline \bullet \\ \hline X \\ \hline X \\ \hline X \end{array} \stackrel{(F^\circ)}{=} \begin{array}{c} X \\ \hline \bullet \\ \hline X \\ \hline X \\ \hline X \end{array}$$

Functorial semantics for relational theories

- A la Lawvere, once you know that the notion of cartesian bicategory replaces cartesian category
 - term syntax is given by string diagrams
 - models are functors of cartesian bicategories to **Rel**
 - homomorphisms are the canonical notion of natural transformation
- completeness (CSL 2018)
- This same general functorial semantics recipe is repeated for partial algebraic theories (PoPL 21) and coherent theories (PoPL 23)

Two starting points

- Aurelio Carboni and RFC Walters (1987) Cartesian Bicategories
 - an algebra of relations with the expressive power of regular logic
- **Charles Peirce's Calculus of Relations (1883)**
 - **featuring linear distributivity and linear adjoints**

Aside: **Rel**'s weird cousin

- From now on let us call the usual category of relations **Rel**[◦]
- Lets meet its strange cousin, **Rel**[•]
 - objects are still sets and arrows are still relations
 - composition is $x (R ; S) z$ iff $\forall y. xRy \vee ySz$
 - identities are $x \mid y$ iff $x \neq y$
 - cartesian product on objects still makes it a symmetric monoidal category, and homsets are posets
- But it is a **cocartesian bicategory** (the inequalities go the other way!)

Peirce's calculus of relations (1883)

- Peirce liked the weird cousin

$$E ::= R \mid id^\circ \mid E \circ E \mid id^\bullet \mid E \bullet E \mid \perp \mid E \cup E \mid \top \mid E \cap E \mid E^\dagger \mid \bar{E}$$

- The calculus only deals with binary relations. Peirce did not like this and went on to work on **existential graphs** (19th century string diagrams)
- Later work on relational calculi (e.g. Tarski) discarded the “black” structure

Diagrams in Rel•

- Use black background/white strings to emphasise the “De Morgan” aspects

- but how to understand two compositions and two tensors together?

(symmetric monoidal) Linear bicategories

- obvious extension of Cockett, Koslowski, Seely 2000
- linear distributivity

- and linear strengths for tensors
- + obvious laws for identities and symmetries

First order bicategories

- The missing thing is to characterise how the two (co)cartesian structures interact:
- there are **linear adjunctions**

• e.g.

$$\begin{array}{c} X \\ \hline X \end{array} \stackrel{(\tau \triangleleft^\circ)}{\leq} \begin{array}{c} \square \\ \circ \quad \circ \\ \hline \end{array} X \quad \begin{array}{c} X \\ \square \\ \hline X \end{array} \stackrel{(y \triangleleft^\circ)}{\leq} \begin{array}{c} \blacksquare \\ \hline \blacksquare \end{array} X$$

- ... and “linear” Frobenius

$$\begin{array}{c} X \\ \square \\ \hline X \end{array} \stackrel{(F \bullet \circ)}{=} \begin{array}{c} \square \\ \circ \quad \circ \\ \hline \end{array} X \quad \begin{array}{c} X \\ \blacksquare \\ \hline X \end{array} \stackrel{(F \bullet \circ)}{=} \begin{array}{c} \blacksquare \\ \hline \blacksquare \end{array} X$$

Summarising

Worked example

Highlights

- Gödel completeness by adapting Henkin's proof to the string diagrammatic language (more on this on the next slide)
- Functorial semantics for first order theories following the usual recipe
- No variables, no quantifiers
 - Easy and natural encodings of other variable free approaches (e.g. Quine predicate functor logic)

What's new, different?

- Diagrammatic syntax is closely related to Peirce's existential graphs
 - Although negation **is not** a primitive
 - it is a derived operation that operates on syntax
 - e.g. $\neg\neg\neg\phi$ is **syntactically equal** as a diagram to $\neg\phi$
- string diagrams let one to discover places where the traditional syntax has caused problems
 - trivial vs contradictory theories is a meaningful distinction
- trivial theories are propositional logic
 - our axiomatisation becomes Guglielmi's deep inference Calculus of Structures (SKSg)
- completeness theorem extends Gödel's to all theories
